# 1 Introduction

## 1.1 Project Overview

The sinking of the RMS Titanic is one of the most infamous shipwrecks in history. On April 15, 1912, during her maiden voyage, the Titanic sank after colliding with an iceberg, killing 1502 out of 2224 passengers and crew. This sensational tragedy shocked the international community and led to better safety regulations for ships.

In my view, it is a classification problem. We should build a classification model, then we can predict the passenger survived or not by passenger features like Pclass, Sex and so on. The problem comes from kaggle. I download the related dataset from kaggle[1].

## 1.2 Problem Statement

In this project, I am going to complete the analysis of what sorts of people were likely to survive. In particular, I will apply the tools of machine learning to predict which passengers survived the tragedy.

## 1.3 Metrics

In this project, I will choose the F1 score[1] for the result. The F1 score can be interpreted as a weighted average of the precision and recall, where an F1 score reaches its best value at 1 and worst score at 0. The relative contribution of precision and recall to the F1 score are equal. The formula for the F1 score is:

$$F1Score = 2 * (precision * recall) / (precision + recall)$$

I want to add something about the advantage of F1 Score. We know that accuracy just cares about how many data are correctly predicted and sometimes it is not suitable. But F1 Score takes not only precision into consideration but also recall. Therefore, I think this time F1 Score can evaluate the performance better about classifier.

# 2 Analysis

## 2.1 Data Exploration

In this part I will do data engineering. Above all, I will show the features of the data sets. As you can see, each passenger has eleven features. The statistical information can be seen in figure 1. The meaning of features can be seen below.

	PassengerId	Survived	Pclass	Age	SibSp	Parch	Fare
count	891.000000	891.000000	891.000000	714.000000	891.000000	891.000000	891.000000
mean	446.000000	0.383838	2.308642	29.699118	0.523008	0.381594	32.204208
std	257.353842	0.486592	0.836071	14.526497	1.102743	0.806057	49.693429
min	1.000000	0.000000	1.000000	0.420000	0.000000	0.000000	0.000000
25%	223.500000	0.000000	2.000000	NaN	0.000000	0.000000	7.910400
50%	446.000000	0.000000	3.000000	NaN	0.000000	0.000000	14.454200
75%	668.500000	1.000000	3.000000	NaN	1.000000	0.000000	31.000000
max	891.000000	1.000000	3.000000	80.000000	8.000000	6.000000	512.329200

Figure 1: Full\_Data

1. survival : Survival (0 = No; 1 = Yes)
2. pclass : Passenger Class (1 = 1st; 2 = 2nd; 3 = 3rd)
3. name : Name
4. sex : Sex
5. age : Age
6. sibsp : Number of Siblings/Spouses Aboard
7. parch : Number of Parents/Children Aboard
8. ticket : Ticket Number
9. fare : Passenger Fare
10. cabin : Cabin
11. embarked : Port of Embarkation (C = Cherbourg; Q = Queenstown; S = Southampton)

You can see the table 1 that i select the null from the data,if the value is false it means that the values don't have nan,if it is true,it has nan.We can learn from the table that there are some missing values in Age,Cabin and Embarked.And we can know that the Age,Fare and Family have outliers i will process in next section.

## 2.2 Exploratory Visualization

This time i will use seaborn[2] to plot figures.

Figure 2 is about age and sex. We can obviously find that female survived more than male. Maybe male choose to let female go that time. That's truly gentleman.

Figure 3 is about the Embarked. From the picture we can learn that when Embarked is C it has the highest mean of survived.

Figure 4 is about Pclass and Fare, i want to explore if people cost more money have higher probability survived. And i find that when class is 1 it have more probability to survive cause it close to sky.

Figure 5 is about Family and Age, i want to find that if people have more sisters or parents in the ship have higher probability to survive. And i find the truth is that people have many relatives do not survive may be it because people can't go themselves.

Figure 2: Age-Sex

PassengerId	Survived	Pclass	Name	Sex	Age
False	False	False	False	False	True
SibSp	Parch	Ticket	Fare	Cabin	Embarked
False	False	False	False	True	True

Table 1: Missing Values

Figure 3: Embarked

Figure 4: Pclass-Fare

## 2.3 Algorithms and Techniques

In order to have a good prediction,i will choose a good model first.And now i will test three models to train.Then i will choose best of these to tune. The models are SVM[3],KNN[4] and RandomForest[5] for my models. And i will say something about these three algorithms.After that,i will use linear model to be the benchmark.

SVM:

- SVM maps samples to Hilbert space and use this way to make data become linear separable,the use margin to separate data.Besides,different kernels can build different svms.
- In general application,we may consider use SVM to predict if students grade can pass the test,because students have many features like age,the education of parents,spend how much time studying and so on,SVM can be used for classification and regression.
- It is effective in high dimensional spaces,and have a good margin.So if we have many features it may perform well.
- When the number of features is much greater than the number of samples, it may give bad performances.

KNN:

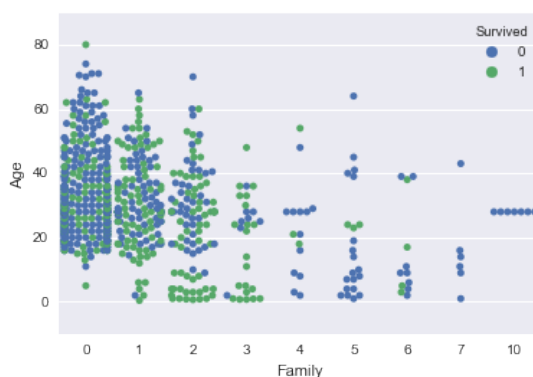

Figure 5: Family-Age

- KNN works like this example,if there are three rich people is very close to me,then it will think i am also a rich man.
- In general application,we can use it to predict the prices of house,knn can be used for regression.
- It has low cost if we need to re-practice.When the data have many overlapping features it may perform well.
- It's a lasy learner and if the data is not balanced it may give bad performances.

RandomForest:

- RandomForest means use a lot of trees to train and predict the classifier.First it sample subdataset then use these to build subtree,then it choose best features to becaome the splitting features.
- In general application,we can use RandomForest to predict if the passengers can survive in diaster using different features like sex,age and so on.
- It is very efficient to train and make a prediction.And it won't suffer from overfitting because it actually add the margin of each features.
- It is consisted of different weak learners which may be have a little more than 50% successful prediction ability and finally it become a strong learner.

## 2.4 Benchmark

I will test the f1 score of each model and find the best one.As we can see in table 2,a linear model has F1 Score 0.5049 for training and 0.5047 for test.Therefore,i will set the benchmark as the f1 score of each model and set the threshold as 0.505.

Model	Size	Time	Train Score	Test Score
Linear	100%	0.0054s	0.505	0.505

Table 2: Linear Model

## 3 Methodology

### 3.1 Data Preprocessing

Above all, i will tell what i have done for data.  
I change all string features into numerical features.

1. I let NaN in Age equals to the mean of Age.
2. I let Embarked equals to 0,1,2 when the value is S,C,Q.
3. I let Sex equals to 0,1 when it is male and female.
4. I Add new features Family equals to SibSp add Parch.
5. I delete PassengerId,Name,SibSp,Parch,Cabin and Ticket.

It's easy to understand i change features into numerical,and i want to explain why i delete other features.To be honest,I think that the Cabin has a lot of null value which means little information.Besides,Name,Ticket is irregular.Therefore,i decide to delete these features.And i want to note that people can have age less than 1 because they are baby.

As for outliers,in my opinion,i have two reasons not to delete.First,there are little data which is both outliers for two or more features.Second,i think each people has his value,i want to take them into consideration.

### 3.2 Implementation

This part i will tell the process for which metrics, algorithms, and techniques. Firstly,i learn from sklearn and create three different models using their algorithm,then i also use the f1 score of sklearn to judge if this model can satisfy the benchmark and my threshold value.

SVM:

- Using from sklearn import svm to import svm
- Using clf = svm.SVC() to create classifier
- C=1.0,kernel=rbf,degree=3,gamma=auto and so on

KNN:

- Using `from sklearn.neighbors import KNeighborsClassifier` to import
- Using `clf = KNeighborsClassifier()` to create classifier
- `n_neighbors=5,leaf_size=30,metric=mnikowski` and so on

RandomForest:

- Using `sklearn.ensemble import RandomForestClassifier` to import
- Using `clf = RandomForestClassifier()` to create classifier
- `n_estimators=10,criterion=gini,max_features=auto` and so on

More details can be seen in my Titanic.ipynb.

Besides in order to have a good train and test set,i use `train_test_split[6]` to split data.

And i use three times to test the models,and here are the table.

Models	Size	Time	Train Score	Test Score
SVM1	33%	0.008s	0.877	0.381
SVM2	66%	0.020s	0.855	0.400
SVM3	100%	0.027s	0.880	0.404
KNN1	33%	0.002s	0.634	0.565
KNN2	66%	0.001s	0.693	0.560
KNN3	100%	0.001s	0.736	0.574
Ran1	33%	0.024s	0.971	0.635
Ran2	66%	0.024s	0.969	0.773
Ran3	100%	0.033s	0.965	0.730

Table 3: Comparision Of Models

As we can see in the table,randomforest algorithm have the best test score,so i will choose it for my next model.

### 3.3 Refinement

Since i have choose the randomforest,now i will tune model for better results. In order to get the best parameters,i will use grid search[7] and cross validation[8] to avoid overfitting.

What i am going to change can be seen below:

- n\_estimators:10,20,40,80
- criterion:gini,entropy
- max\_features:log2,sqrt,None
- max\_depth:5,6,7,8
- min\_sample\_split:1,2,3
- warm\_start:False,True

I will explain the meaning of each parameter.

- n\_estimators means the number of trees in the forest.
- criterion means the function to measure the quality of a split. item max\_features means the number of features to consider when looking for the best split.
- max\_depth means the maximum depth of the tree.
- min\_samples\_split means the minimum number of samples required to split an internal node.
- warm\_start means if reuse the solution of the previous call to fit and add more estimators to the ensemble.

I will tell what will happen if i change the parameters of the RandomForest model.I will give some examples, firstly if i increase the n\_estimators it will add the number of trees,the more tree it have,the more weaker learner it will have.As for max\_depth,if i increase it,it will ask more question to it self,however if it is to large,the model may suffer from overfitting.

After 663.57s searching,i finally get the optimal model parameters.The value can be seen below.

- 'warm\_start': True

- 'oob\_score': False
- 'n\_jobs': 1,
- 'verbose': 0
- 'max\_leaf\_nodes': None
- 'bootstrap': True
- 'min\_samples\_leaf': 1
- 'n\_estimators': 40
- 'min\_samples\_split': 2
- 'min\_weight\_fraction\_leaf': 0.0
- 'criterion': 'entropy',
- 'random\_state': None
- 'max\_features': 'sqrt'
- 'max\_depth': 8
- 'class\_weight': None

I get the final f1 score is 0.735 which is better than previous test. And comparing it to threshold it is higher than threshold. Therefore I think this model is significant enough to deal with the problem. To be more detailed, I use a random forest model having 40 trees and it asks 8 questions for each data.

You can see the figure 6 that when it is time to test the tuned model has the highest score.

## 4 Result

### 4.1 Model Evaluation and Validation

Here you can see my model's learning curves in figure 7. At first, training score is high, but cross validation score is low. With the increasing of training samples, the training score starts to decrease and the cross validation score starts to increase and it shows the tendency of convergence.

Figure 6: Model-Comparison

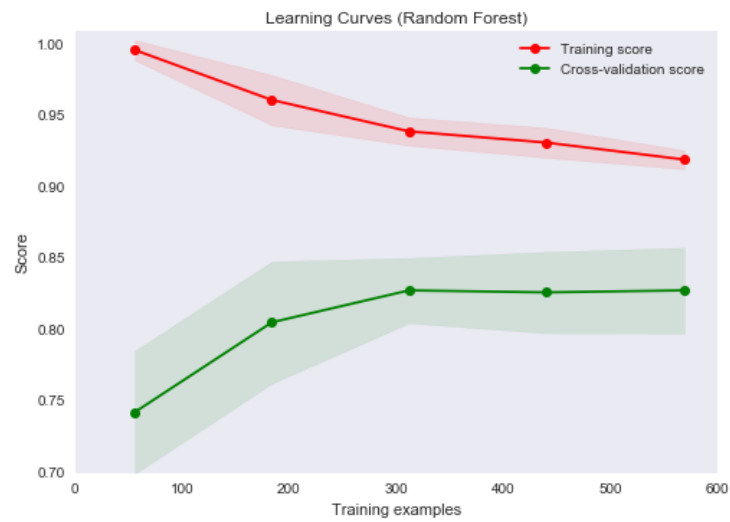

Figure 7: Learning Curves

## 4.2 Justification

We can see the figure learning curves which shows the robustness of my random forest model which show the tendency of convergence. So i think after my long time tuning me model can work well with the data. Besides, the f1 score is higher than my benchmark. Therefore i think this model can solve the prediction problem of passengers.

## 5 Conclusion

You can see the figure 6 Model-Evaluation which shows that my tuned model really does better than previous. And it can be known from the higher f1 score. As for my process, i first explore the data, then do feature engineering adding or deleting some features. After that, i firstly choose three model to find the best one. Then i tune the best randomforest model to get best results. Obviously my model works better than ever.

The interesting thing i think is to find the best parameters, firstly i just tune the model by hand. For example, i change the init function to change parameters. And i find it is too hard and too boring. Fortunately, i think of Grid Search and use it to instead my hand.

In order to improve the result, i think we can add more parameters. For example, we can add more detailed parameters like n\_estimators: 10, 20, 30, 40, 50 and so on. Of course it will cost much more time.

As for improvement, i think we may can create a weighted random forest to improve the predictive performance[9]. The main idea of it is incorporate tree-level weights to emphasize more accurate trees in prediction and calculation of variable importance. Therefore, i think if we can use this new model to predict the result we may can get a better result.
